

Leva.Framework.Sample.StorageDesk

Web sample for Storage, Identity.Memory, and Notifications.Memory. It runs the same ticket flow against memory, file, and SQLite storage providers.

```
Leva.Framework.Sample.StorageDesk
    -> Leva.Framework.Core
    -> Leva.Framework.Storage
    -> Leva.Framework.Storage.Memory
    -> Leva.Framework.Storage.Files
    -> Leva.Framework.Storage.Sqlite
    -> Leva.Framework.Identity
    -> Leva.Framework.Identity.Memory
    -> Leva.Framework.Notifications
    -> Leva.Framework.Notifications.Memory
    -> Microsoft.AspNetCore
```

Setup shown by the sample

```
StorageDeskRunner
    -> creates MemoryPrincipalServices
    -> creates MemoryNotificationServices
    -> logs in a manager principal
    -> creates memory, file, and SQLite storage providers
    -> passes IRepository<string, Ticket> and IJournal<TicketActivity> to StorageDeskApp
p

StorageDeskApp
    -> uses PrincipalAccess to require tickets.manage
    -> saves Ticket through IRepository
    -> appends TicketActivity through IJournal
    -> sends assignment and resolution notifications through NotificationService
```

Behavior shown

New ticket	-> Assigned ticket	-> Resolved ticket
Repository save	-> Journal activity	-> Notification entry
memory	-> files	-> sqlite

Each storage provider runs the same application flow. The sample checks that the ticket is saved, two activity entries are written, and two notification entries are stored.

Run and expected result

```
dotnet run --project samples/Leva.Framework.Sample.StorageDesk
```

```
memory: PASS
  files: PASS
  sqlite: PASS
  two activity entries per provider
  two notification entries per provider
Sample result: PASS
```
