

Leva.Framework.Storage.Memory

`Leva.Framework.Storage.Memory` is the in-memory provider implementation of `Leva.Framework.Storage`. It stores repositories and journals in process for tests, demos, samples, and short-lived hosts.

```
Leva.Framework.Storage.Memory
    -> Leva.Framework.Core
    -> Leva.Framework.Storage
```

Project overview

The memory provider is a complete provider for the storage contracts. It keeps named repositories and journals inside one provider instance. Repositories store keyed values with per-record versions, while journals append ordered entries with sequence versions.

The provider is intentionally not durable. It is useful when a host needs the same storage contracts without file, database, or EF Core setup.

Files and classes

Provider composition

`MemoryStorageProvider` - Creates repository and journal contracts for one in-memory provider instance. `MemoryStorageDatabase` - Owns named in-memory repository and journal stores for one provider instance.

Repository implementation

`MemoryRepository<TId, TValue>` - Internal repository implementation that delegates keyed value operations to a named in-memory store. `MemoryRepositoryStore<TId, TValue>` - Holds repository entries, performs version checks, and returns snapshots of stored values.

Journal implementation

`MemoryJournal<TEntry>` - Internal journal implementation that delegates append and read operations to a named in-memory store. `MemoryJournalStore<TEntry>` - Holds journal entries and assigns sequence versions.
